Abstract

Maximum probability of existence of cancer in human bodies is normally diagnosed very late, so that, it is highly cumbersome for physicians to cure. Reliability in predicting cancer at initial stage is always needed, so that curing and medical recovery is possible. In this paper, an investigation was made to diagnose the presence of primary tumor using MCMC Convergence model. The MCMC procedure is used here to carry out the analysis which is most efficient on a wide range of complex Bayesian statistical models. The analysis was carried out using version 18 of SPSS AMOS software. Totally, 18 components were considered for the diagnosis from the primary tumor samples of 725 patients. Patients having primary tumor were analysed considering various factors such as class, age, sex, degree of life, etc. using mathematical modeling techniques. The maximum likelihood estimators (MLEs) of the parameters were derived and assessed their performance through a Monte Carlo simulation study. From the collected information the values of convergence for likelihood of each components of primary tumor has been identified and the results presented.

Key words: Monte Carlo Simulation, Modelling, Cancer, Convergence

1. INTRODUCTION

Recent developments in science and technology in the past few centuries has made it necessary to apply mathematical methods to real-life problems arising from different fields – be it Science, Finance, Management etc. With the advent of computational power of digital computers and computing methods, the use of Mathematics in

solving real-world problems has become widespread, especially for handling of lengthy and complicated problems.

The process of translation of a real-life problem into a mathematical form can give a better representation and solution of certain critical problems. Markov chain Monte Carlo (MCMC) methods are a class of algorithms used for sampling from probability distributions based on constructing a Markov chain as its equilibrium distribution. After a large number of steps / iteration, it is used as a sample of the desired distribution. Based on the number of steps, the quality of the sample improves. The number of steps required is determined based on the convergence to the stationary distribution within an acceptable error.

2. LITERATURE REVIEW

Studies on statistical modelling have been reported by various researchers such as models through Air pollution data, [Cowles et al (2002)] A single MCMC chain, [Sylwestrowicz (1982)], [Adams et al (1996)], [Rossini et al (2003)], [Rosenthal (2000)], [Wilkinson (2005)] Spatial statistical modeling [Whiley and Wilson (2004)], [Blackford et al, (1997)], [Neal (2003)] and Bayesian Spatiotemporal Geo-statistical Model. Research works of Bayesian Analysis of Stochastic Models were carried out in Single Molecule Biophysics. Recent technological advances have allowed scientists to follow a biochemical process on a single molecule basis, unlike traditional macroscopic experiments. These raised many challenging data-analysis problems and called for a sophisticated statistical modeling and inference effort.

In this paper, an investigation was made to diagnose the patients of primary tumor cancer using MCMC Convergence model. 18 components were considered for the diagnosis from the primary tumor samples of 725 patients. Patients having primary tumor cancer were analysed considering various components such as class, age, sex, degree of life, etc. using mathematical modeling techniques. The maximum likelihood estimators (MLEs) of the parameters were derived and assessed their performance through a Monte Carlo simulation study. The Bayesian statistical model of MCMC procedure is used in this analysis, which enables us to carry out analysis on a wide range of complex data. The analysis was carried out using version 18 of SPSS AMOS software.

3. DATA PROCESSING AND ANALYSIS

Amos provides several diagnostics that help anyone check convergence. The patients having primary tumor components were taken into account. Class: lung, head and neck, esophagus, thyroid, stomach, duodenum and 5m. int, colon, rectum, anus, salivary glands, pancreas, gallbladder, liver, kidney, bladder, testis, prostate, ovary, corpus, uteri, cervix uteri, vagina and breast. Age: <20, 20-59, greater than or equal to 60. Sex: Male, Female. Histologic-type (epidermoid, adeno, anaplastic). Degree of life (well, fair, poor), bone (yes, no), bone-marrow (yes, no), lung (yes, no), pleura (yes, no), peritoneum (yes, no). liver (yes, no). brain (yes, no). skin (yes, no). neck (yes, no). supraclavicular (yes, no), axillar (yes, no), mediastinum (yes, no),

abdominal (yes, no). All types of the patients in all types of primary tumor were strongly diagnosed through the model.

Bayesian analysis requires estimation of explicit means and intercepts. Before performing any Bayesian analysis in Amos, we have to first tell Amos to estimate means and intercepts. Amos displays Estimates, Scalar Estimates, Maximum Likelihood Estimates, and Regression Weights. F1-F2 diagram is then obtained after analyzing the tables in Amos and given in Fig. 1. In F1-F2 diagram, F2 contains class, age, sex and type while F1 includes all other components for analyzing primary tumor cancer. Regression weights, Intercepts, Co-variances and Variance are predicted by AMOS software and the results are presented in Table 1.

4. RESULTS AND DISCUSSIONS

On the toolbar of the Bayesian SEM window, AMOS presented a convergence value (C.S) of 1.0083. This is an overall convergence based on the statistical analysis. Each time the screen refreshes, Amos updates the C.S. for each parameter in the summary table; the C.S. value on the toolbar is the largest of the individual C.S. values. The C.S. compares the variability within parts of the analysis sample to the variability across these parts. By this standard, the maximum C.S. of 1.0083 is not small enough, then the fitness displays an unhappy face.

5. CONCLUSIONS

From all the collected information and the statistical analysis carried out using AMOS, each component of primary tumor has the maximum C.S. which is strictly less than 1.0083. Thus, the patients having primary tumor cancer are strongly diagnosed through the model.
