#### Abstract

A statistical margin of error for the mean of variable $x$ taken from a random sample of size $n$ from a population of interest of very large, possibly infinite, size can be presented as an extension of the Pythagorean distance between two vectors, where one vector, $\mathrm{V}_{\mathrm{m}}$, represents the mean of the random sample, and the other, $\mathrm{V}_{1}$, is found by summing the n values of x and letting these n summed values form the elements of $\mathrm{V}_{1}$,

Suppose we have a random variable, x , where the values of x taken from a random sample of size n from a population of size N , where N is possibly infinite, but at the least very large and not necessarily known. Let the sum of the n values of random variable x equal $\Sigma \mathrm{n}_{\mathrm{i}}$. These same n values form the n elements of vector $\mathrm{V}_{1}$, There are exactly $\mathrm{n}-1$ additional distinguishable vectors, $\mathrm{V}_{2}, \mathrm{~V}_{3}, \ldots, \mathrm{~V}_{\mathrm{n}}$, that can be formed by permuting the $n$ elements of $V_{1}$ such that $V_{1}+V_{2}+V_{3}+, \ldots,+V_{n}=\left(\Sigma n_{1},, \Sigma n i_{2}, \Sigma n i_{3}\right.$, ,$\left.\Sigma \mathrm{ni}_{\mathrm{n}}\right)=\mathrm{V}_{\mathrm{s}}$. Multiplying $\mathrm{V}_{\mathrm{s}}$ by the scalar $(1 / \mathrm{n})$ gives $\mathrm{V}_{\mathrm{m}}$, the point in $\mathrm{n}-$ space that is $(1 / n)^{\text {th }}$ the distance from the origin to $\mathrm{Vs} . \mathrm{V}_{\mathrm{m}}$ can be interpreted as the mean of the random sample of size $n$.
Now consider an infinite number of random samples of size n from a population of size N , where N is possibly infinite, but at the least very large and not necessarily known, for which this same process was repeated. Let the mean of all of these sample means be $\mathrm{V}_{\mathrm{n}}$, which is equal to the mean of the entire population. Because we have an infinite number of samples, $\mathrm{V}_{\mathrm{n}}$, is unknown to us but of interest. We can estimate the distance from $\mathrm{V}_{\mathrm{m}}$ to $\mathrm{V}_{\mathrm{n}}$ with a selected degree of probability and an extension of this distance can be viewed as the Margin of Error, a statistic expressing the level of confidence in the estimate of the distance between $\mathrm{V}_{\mathrm{m}}$ to $\mathrm{V}_{\mathrm{n}}$.

How can we do this? First, Let $D$ equal the Pythagorean distance between $\mathrm{V}_{1}$ and $\mathrm{V}_{\mathrm{m}}$.

We then multiply $D$ by the scalar $(1 / n)^{1 / 2}$, which allows us to present the standard deviation of our random sample as $s=(1 / \mathrm{n})^{1 / 2}(D)$. It follows that the standard error associated with our sample mean, $\mathrm{V}_{\mathrm{m}}$, is $s e=D$. With a given level of certainty, knowledge of $D$ allows us to assess how far $\mathrm{V}_{\mathrm{m}}$ is from $\mathrm{V}_{\mathrm{n}}$. We can do by constructing a "Margin of Error," (MOE). If $\mathrm{n} \leq 120$, then $\mathrm{MOE}=t_{c} D$, where $t_{c}$ can be taken from a "student's t table" as found in Spiegel [1, p.344]. If, for example, $\mathrm{n}=25$ and we want to be $95 \%$ certain of the distance between $\mathrm{V}_{\mathrm{m}}$ and $\mathrm{V}_{\mathrm{n}}$, then we select $t_{c}=2.06$.

If $\mathrm{n}>120$, then $\mathrm{MOE}=z_{c} D$, where $\mathrm{z}_{\mathrm{c}}$ is taken from a " z table" as found in Spiegel [1, p. 343] Thus, if $n>120$ and we want to be $95 \%$ certain of the distance between $V_{m}$ and $\mathrm{V}_{\mathrm{n}}$, then we select $z_{c}=1.96$.

Thus, from the perspective of geometry (and linear algebra), an MOE is an extension of D , where the extension is determined by n and the level of confidence we want in terms of the distance between $\mathrm{V}_{\mathrm{m}}$ and $\mathrm{V}_{\mathrm{n}}$. Note that if $\mathrm{D}=$ zero, random variable x is a constant value, k , which implies $\mathrm{V}_{\mathrm{m}}=\mathrm{V}_{\mathrm{n}}$.
